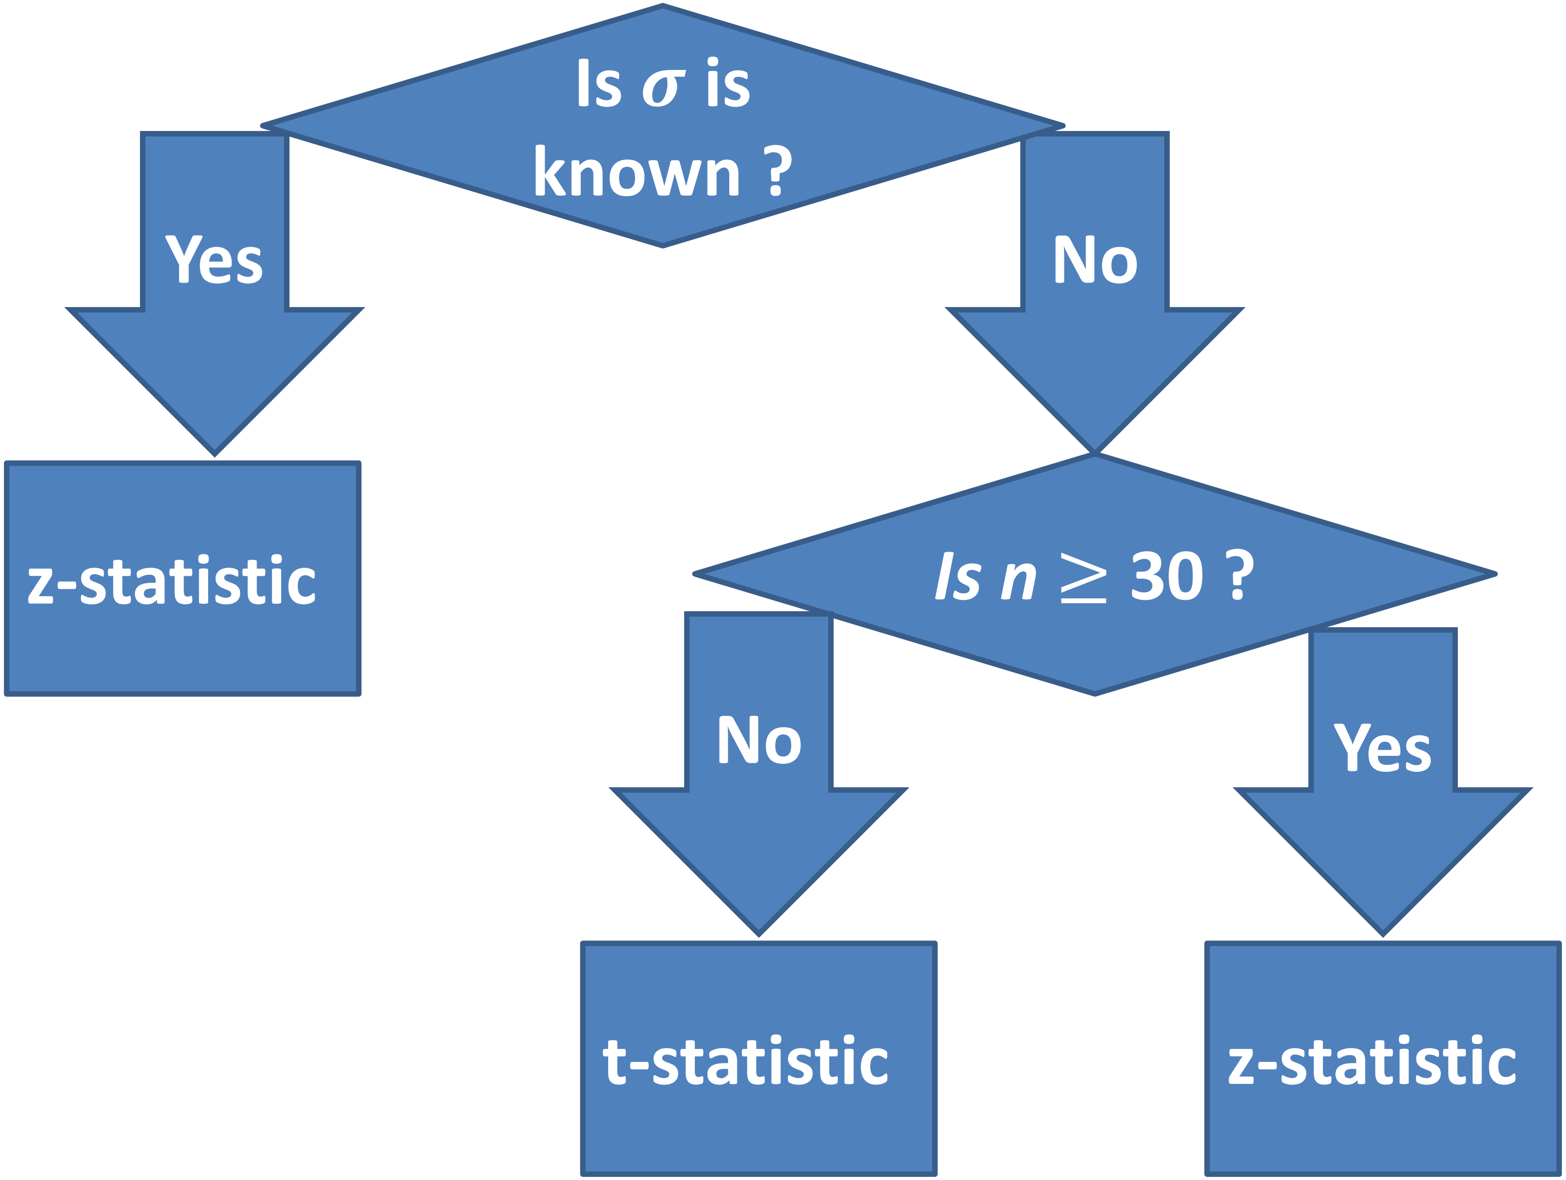
These notes contain material from the above resources.



Is σ is known ?
Yes
No
z-statistic
Is $n \geq 30$?
No
Yes
t-statistic
z-statistic

$$Z_{cal} = \frac{\bar{x} - \mu}{\sigma/\sqrt{n}}$$

$$Z_{cal} = \frac{\bar{x} - \mu}{s/\sqrt{n}}$$

$$S = \sqrt{\frac{\sum(\mathbf{x} - \bar{x})^2}{n}}$$

$$S = \sqrt{\frac{1}{n}\left\{\sum_{i=1}^{n} \mathbf{x}^2 - \frac{(\sum_{i=1}^{n} \mathbf{x})^2}{n}\right\}}$$

$$t_{cal} = \frac{\bar{x} - \mu}{s/\sqrt{n}}$$

$$s = \sqrt{\frac{\sum(\mathbf{x} - \bar{x})^2}{n-1}}$$

$$s = \sqrt{\frac{1}{n(n-1)}\left\{n\sum_{i=1}^{n} x^2{}_i - \left(\sum_{i=1}^{n} x_i\right)^2\right\}}$$

A ***P*-value** is the **lowest level (of significance)** at which the observed value of the test statistic is significant.

***P*-value method:**

- ***Reject H_0*** if the ***P*-value** $\leq \alpha$ (where α is the significance level, such as 0.05).

- ***Fail to reject H_0*** if the ***P*-value >** α**.**

Procedure for Finding *P*-Values

EXAMPLE Finding *P*-Values First determine whether the given conditions result in a **right-tailed test,** a **left-tailed test**, or a **two-tailed test**, then use Figure 1 in the previous slide to find the *P*-value, then state a conclusion about the null hypothesis.

a. A significance level of $\alpha = 0.05$ is used in testing the claim that $p > 0.25$, and the sample data result in a test statistic of $z_{cal} = 1.18$.

b. A significance level of $\alpha = 0.05$ is used in testing the claim that $p \neq 0.25$ and the sample data result in a test statistic of $z_{cal} = 2.34$.

a. With a claim of $p > 0.25$, the test is right-tailed.

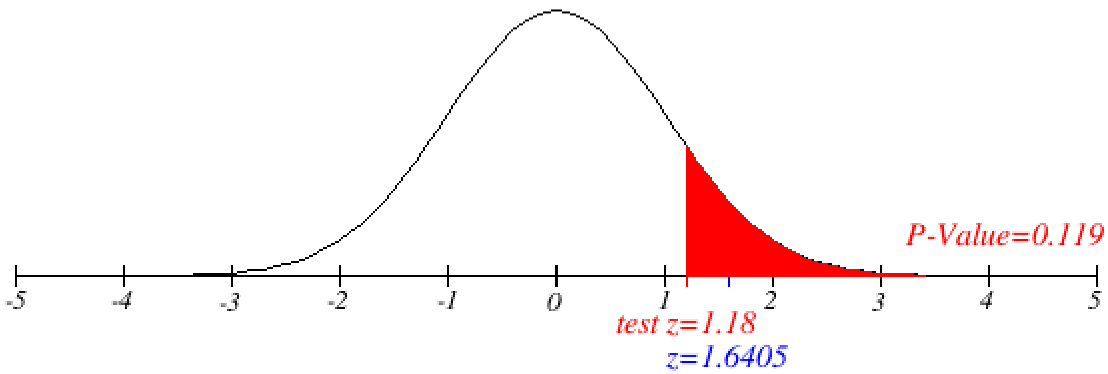
Z_{cal} = 1.18

$P(Z_{cal} > 1.18) = 1 - P(Z_{cal} < 1.18)$

$= 1 - .8810$

$= 0.1190$

P-value = 0.1190



***P*-value $\leq \alpha$**

$0.1190 \leq 0.05$ (false)

We fail to reject the null hypothesis.

- **The *P*-value of 0.1190** is **relatively large**, indicating that the sample results **could easily occur by chance**.

b With a claim of the test is two-tailed. Using Figure 1 for a two tailed test, we see that the *P*-value is *twice* the area to the right of $z_{cal} = 2.34$.

$P(|Z_{cal}| > 2.34) = 1 - P(|Z_{cal}| < 2.34)$

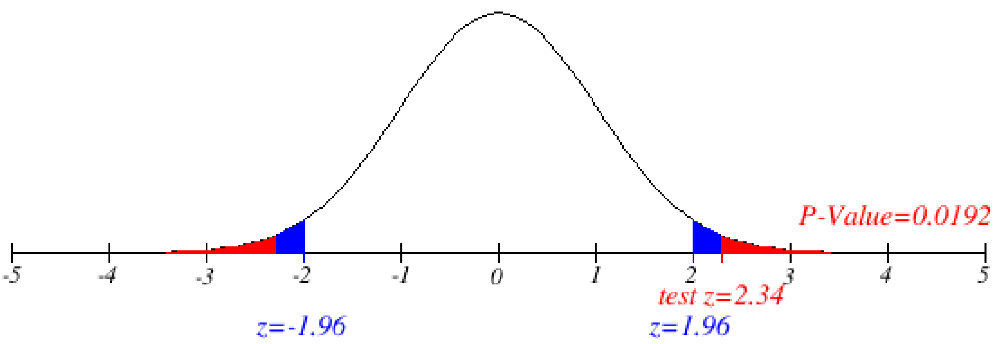
$= 1 - 0.9904$

$= 0.0096$

$\text{P-value} = 2 \times P(|Z_{cal}| > 2.34)$

$\text{P-value} = 2 \times 0.0096$

$= 0.0192$



$P\text{-value} \le \alpha$

$0.0192 \le 0.05$ **(true)**

We reject the null hypothesis.

- ❑ The **small *P*-value** of **0.0192** shows that the sample results are not likely to occur by chance.

Single Sample: Tests Concerning a Single Mean

Example: A random sample of 100 recorded deaths in the United States during the past year showed an average life span of 71.8 years. Assuming a population standard deviation of 8.9 years, does this seem to indicate that the mean life span today is greater than 70 years? Use a 0.05 level of significance.

Solution:

n =100 (sample size)

$\bar{x} = 71.8$ (sample mean)

σ = 8.9 (population standard deviation)

α = 0.05 (level of significance)

1. **We state our hypothesis as**:

H_0: μ = 70 years

H_1: μ > 70 years (one sided test)

2. **The level of significance is set** $\alpha = 0.05$.

3. **Test statistic to be used is**

$$Z_{cal} = \frac{\bar{x} - \mu}{\sigma/\sqrt{n}}$$

4. **Calculations:**

$$Z_{cal} = \frac{71.8 - 70}{8.9/\sqrt{100}} = 2.02.$$

5. **P-value**

$\mathbf{Z_{cal} = 2.02}$

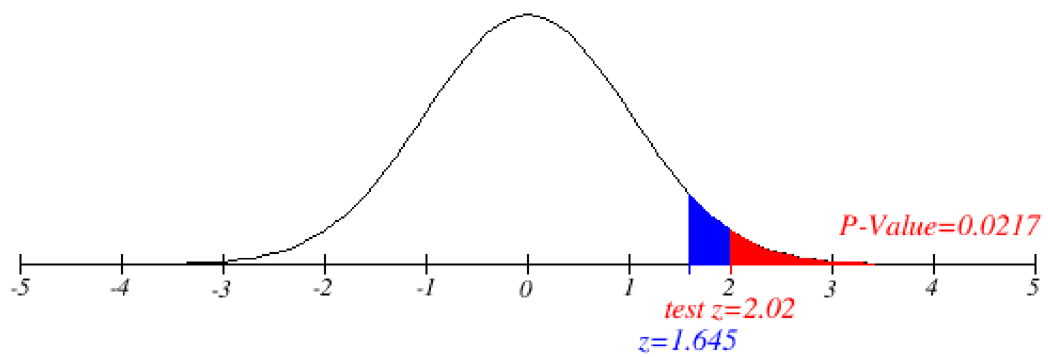
$P(Z_{cal} > 2.02) = 1 - P(Z_{cal} < 2.02)$

$= 1 - 0.9783$

$= 0.0217$

***P*-value $\leq \alpha$**

$0.0217 \leq$ **0.05 (true)**



6. **Conclusion:** We reject $\mathbf{H_o}$

Example: A manufacturer of sports equipment has developed a new synthetic fishing line that the company claims has a mean breaking strength of **8 kilograms** with a **standard deviation of 0.5** kilogram. Test the hypothesis that $\mu = 8$ kilograms against the alternative that $\mu \neq 8$ kilograms if a random sample of **50 lines** is tested and found to have a mean breaking strength of **7.8 kilograms**. Use a 0.01 level of significance.

Solution:

$\mu = 8$ (Population mean)

$n = 50$ (Sample size)

$\sigma = 0.5$ (Population standard deviation)

$\bar{x} = 7.8$ (Sample mean)

$\alpha = 0.01$ (Level of significance)

1. **We state our hypothesis as**:

H_0: $\mu = 8$

H_1: $\mu \neq 8$ (Two sided test)

2. **The level of significance is set** $\alpha = 0.01$.

3. **Test statistic to be used is**

$$Z_{cal} = \frac{\bar{x} - \mu}{\sigma/\sqrt{n}}$$

4. **Calculations:**

$$Z_{cal} = \frac{7.8 - 8}{0.5/\sqrt{50}} = -2.83.$$

$Z_{tab} = 2.575$

5. P-value

z_{cal} **= 2.83**.

P(|Z_{cal} |> 2.83) = 1 – P(|Z_{cal} | < 2.83)

= 1 – 0.9977

= 0.0023

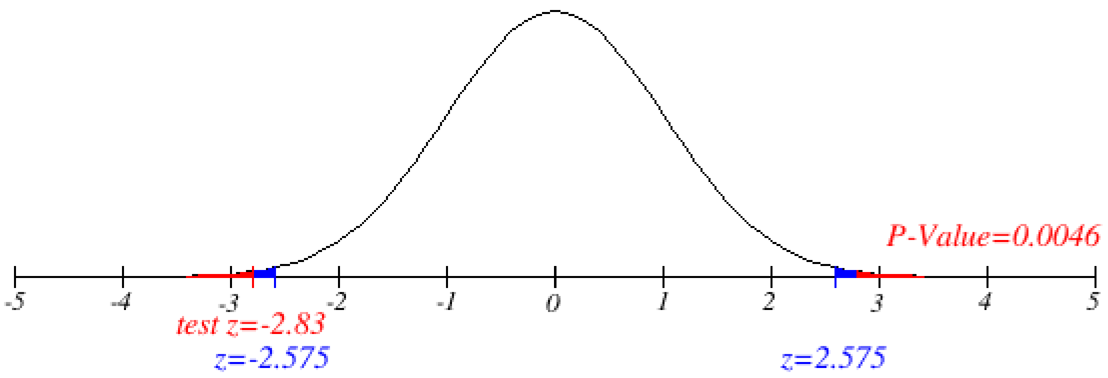
P-value = 2 × **P(|Z_{cal} | > 2.83)**

P-value = 2 × 0.0023

= 0.0046

***P*-value ≤ α**

0.0046 ≤ 0.05 (true)



6. **Conclusion:** We reject H_O

Example: The Edison Electric Institute has published figures on the number of kilowatt hours used annually by various home appliances. It is claimed that a vacuum cleaner uses an average of **46** kilowatt hours per year. If a random sample of **12** homes included in a planned study indicates that vacuum cleaners use an average of **42** kilowatt hours per year with a standard deviation of **11.9** kilowatt hours, does this suggest at the **0.05** level of significance that vacuum cleaners use, on average, less than **46** kilowatt hours annually? Assume the population of kilowatt hours to be normal.

Solution

$\mu = 46$	(Population mean)
$n = 12$	(Sample size)
$s = 11.9$	(Sample standard deviation)
$\bar{x} = 42$	(Sample mean)
$\alpha = 0.05$	(Level of significance)

1. **We state our hypothesis as**:

$H_0: \mu = 46$

$H_1: \mu < 46$ (One tailed test)

2. **The level of significance is set** $\alpha = 0.05$.

3. **Test statistic to be used is**

$$t_{cal} = \frac{\bar{x} - \mu}{s/\sqrt{n}}$$

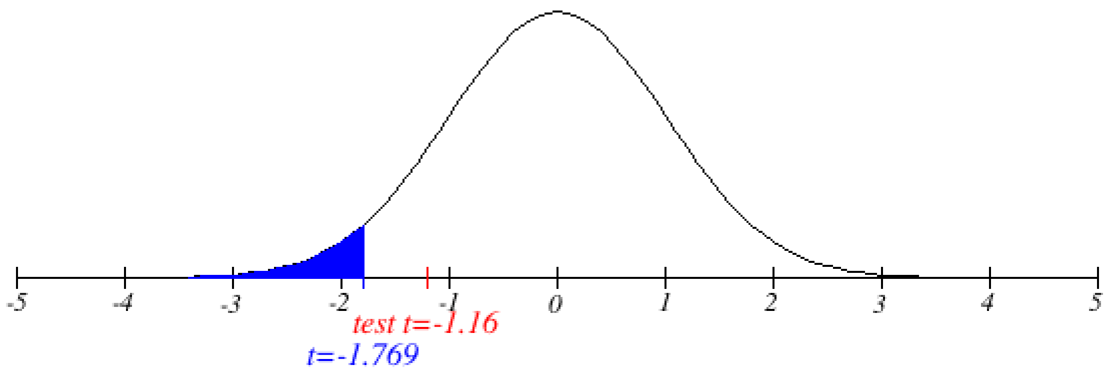
4. **Calculations:**

$$t_{cal} = \frac{42 - 46}{11.9/\sqrt{12}} = -1.16$$

5. **Critical region:**

$t_{cal} < t_{tab}$

Where $-t_{tab} = -t_{(\alpha, n-1)} = -t_{(0.05, 11)} = -1.769$



6. **Conclusion:** Since calculated value of t_{cal} is greater than the tabulate value of t, so we accept H_O
